Despite having used different methodologies, authors who have estimated the future global trends in the frequency of diabetes mellitus generally agree that Asia is the major site of a rapidly emerging epidemic of diabetes. In this issue of the Hong Kong Medical Journal, six articles address the challenge and special features of diabetes mellitus in Asia.

India and China are, and will remain, the leading countries in terms of the number of people with diabetes mellitus in the year 2025. Among the 10 leading countries in this respect, five are in Asia. Although only a moderate increase in the total population in China is expected in the next 25 years, China is estimated to contribute almost 38 million people to the global burden of diabetes in the year 2025. India, due to its immense population size and high diabetes prevalence, will contribute 57 million. These figures are based on estimated population growth, population ageing, and urbanisation, but they do not take into account changes in other diabetes-related risk factors. For this reason, the figures are likely to be conservative estimates.

An increasing incidence of type 2 diabetes mellitus in children and teenagers has been documented in Japan, and is associated with obesity and a family history of diabetes. Although not as high as in Japan, the prevalence of type 2 diabetes is also on the increase in adolescents in Hong Kong. Thus, what is a problem for the minority of youth in the world as a whole, is becoming a problem of the majority in Asia, making all current predictions for the future load of diabetes seem optimistic.

In this issue, Lee et al conclude that obesity, rather than insulin resistance seems to be the strongest link to glucose intolerance and other features of the metabolic syndrome in Hong Kong Chinese. Their results, however, indicate that the criteria of the World Health Organization (WHO) for overweight are too high to identify persons at risk of the development of diabetes, hypertension, and dyslipidaemia in a Chinese population. The authors recommend lowering the WHO cut-off body mass index value for overweight in Chinese populations, but do not opt for a particular value. As similar results have been obtained in Japan, the value of 23 kg/m² may be an appropriate cut-off point for overweight in Asian populations of slender build. Diabetes in Asia has other special features. Type 1 diabetes has a low incidence, and markers of autoimmune β-cell destruction are found in less than one fifth of Chinese children. This finding formed the basis for introducing the new category of ‘idiopathic type 1 diabetes’ which appears in the latest classifications of the American Diabetes Association (ADA) and the WHO.

The Asian-Pacific Type 2 Diabetes Group has recently recommended the use of the new WHO and ADA diabetes diagnostic criteria. However, a substantial proportion of Japanese and Hong Kong Chinese people with diabetes have been found to have a normal fasting plasma glucose level, but an abnormal 2-hour post-load plasma glucose level. Measuring the amount of glycated haemoglobin HbA₁c as well as fasting plasma glucose appears to increase the sensitivity for diagnosing diabetes. However, using the oral glucose tolerance test (OGTT) remains a cheaper and technologically simpler option, and is not as cumbersome as is frequently described. The ADA decision to drop the OGTT in favour of measuring the fasting plasma glucose level alone, needs to be supported by data on the prognostic significance of each test in Asian populations. Such data have been gathered in Europe, Mauritius, Fiji, and Nauru, where the 2-hour post-load plasma glucose level was found to be a better predictor of mortality.

Urbanisation is likely to continue in Asia, but diabetes need not be the price to pay for affluence. Lifestyle, however, is notoriously resistant to change, and public health measures that have been taken so far have been insufficiently systematic and indecisive. Improving public health remains an urgent need, as the looming epidemic of diabetes and its complications threatens to drain finite health care resources. The primary and secondary prevention of diabetic complications is achievable by ensuring good glycaemic control and screening regularly for major complications. And in Hong Kong, effective patient education, periodic assessment, and a built-in mechanism to ensure the compliance of both patients and physicians to the treatment protocol have been shown to improve
the outcome of diabetes. This structured approach needs a suitable framework and in this issue of the Journal, Chan describes the implementation of the shared care model in Hong Kong. Stable patients are discharged into community clinics after structured assessments have been made, and they are followed up according to a mutually agreed protocol between diabetes specialists and general practitioners. These patients return to the hospital clinics for periodic assessments. This approach could ease the burden of specialised services, while still ensuring that specialist services are accessible to the majority of diabetic patients.

The articles in this themed issue are a testament to the importance already accorded to diabetes in Asia and augurs well for concerted intervention aimed at averting the epidemic and for minimising its impact in the future.
